

A Orthogroup occupancy across 2,219 polarized orthogroups

B Functional composition of the two loss events

Panel A: points jittered; occupancy is quantised by panel size. Dashed lines mark the 10 and 70 percent thresholds. Categories A and B additionally require occurrence in free-living genera and are read as branch events; C and D do not. Panel B: Fisher exact test against the retained set, Benjamini-Hochberg corrected. * $q < 0.05$, ** $q < 0.01$, *** $q < 0.001$; stars are omitted where a category is absent from a set. The background is the orthogroups retained across both gut genera, not the genome, so these are differences between lost and retained genes rather than enrichment against a neutral expectation.
